Y-12SITE DOCUMENT RESPONSE CENTER

Peter J. Gross. Director Environmental Protection Division DOE Field Office, Oak Ridge Post Office 2001 Oak Ridge, Tennessee 37831-8738

Dear Mr. Gross:

Annual Emissions Report: Radionuclide National Emission Standards for Hazardous Air Pollutants (NESHAPs)

Attached are the 1990 Radionuclide NESHAPs Annual Emissions Report for the Oak Ridge Reservation, as required by 40 CFR 61.94(a), and a summary of the minor changes made to the report since the draft version was submitted to you on April 19, 1991.

The Annual Reports for the Portsmouth and Paducah Gaseous Diffusion Plants are being submitted to their respective DOE Site Offices. You will be provided copies of those reports concurrently with the site offices.

If you have any questions or require additional information, please contact R. H. Kingrea at 6-6210.

Sincerely,

M. E. Mitchell, Director

and L. Star

Summary of Changes to Annual Report

Listed below is a summary of the changes to the annual report as compared to the initial draft report issued on April 19, 1991:

- 1. Minor editorial and grammatical changes were made throughout the document. No substantive changes were made.
- 2. The distances expressed in the fourth column of all tables in Section II have been changed from distances from the source to the most exposed member of the public to distances from the source to the nearest residence, business, school, or farm.
- 3. Emissions estimates from laboratory hoods at the K-25 Site have been added to the report. These emissions did not contribute significantly to the off-site dose to the public.
- 4. The contribution of dose (in mrem/year) to the off-site public due to small unmonitored sources was added to the Compliance Assessment Section of the report.

U. S. Department of Energy Air Emissions Annual Report (under Subpart H, 40 CFR 61.94) Calendar Year 1990

Section I. Facility Information

Site Description: ORR

The Oak Ridge Reservation (ORR) is located within the corporate limits of the city of Oak Ridge in eastern Tennessee. The ORR consists of approximately 14,300 ha (35,300 acres) of federally owned lands. The ORR site is predominantly to the west and south of the city of Oak Ridge, which has a population of 28,000. Oak Ridge lies in a valley between the Cumberland and southern Appalachian mountain ranges and is bordered on one side by the Clinch River. The Cumberlands are about 16 km (10 miles) northwest; 113 km (70 miles) to the southeast are the Great Smoky Mountains.

Except for the city of Oak Ridge, the land within 8 km (5 miles) of the ORR is predominantly rural, used largely for residences, small farms, and cattle pasture. Fishing, boating, water skiing, and swimming are favorite recreational activities in the area. The approximate location and population of the towns nearest the ORR are Oliver Springs (pop. 3600), 11 km (6.8 miles) to the northwest: Clinton (pop. 5200), 16 km (10 miles) to the northeast; Lenoir City (pop. 5400), 11 km (6.8 miles) to the southwest; and Harriman (pop. 8300), 13 km (8 miles) to the west. Knoxville, the major metropolitan area nearest Oak Ridge, is located about 40 km (25 miles) to the east and has a population of approximately 183,000.

Oak Ridge has a temperate climate with warm, humid summers and cool winters. Spring and fall are usually long, and the weather is normally sunny with mild temperatures. Severe storms such as tornadoes or high-velocity winds are rare. The mountains frequently divert hot, southeasterly winds that develop along the southern Atlantic coast. Oak Ridge is one of the country's calmest wind areas. The atmosphere can be considered to be in an inversion status about 36% of the time. The daily up-and-down valley winds, however, provide some diurnal exchange. The prevailing wind directions are northeasterly (up-valley) and southwesterly (down-valley).

The ORR contains three major operating facilities: Oak Ridge Y-12 Plant (Y-12 Plant), Oak Ridge National Laboratory (ORNL), and Oak Ridge K-25 Site (K-25 Site). In addition to operations at these three installations, DOE is responsible for facilities at the Oak Ridge Associated Universities (ORAU) which handle extremely small quantities of radionuclides for research and training purposes. Annual possession quantities for radionuclides handled at ORAU are well below the annual possession quantities for environmental compliance listed in 40 CFR 61, Appendix E, Table 1. Therefore, emission estimates from the ORAU operations are not included in this report.

Source Description: Y-12 Plant

The Y-12 Plant, which is immediately adjacent to the city of Oak Ridge, has five major responsibilities: (1) to fabricate nuclear weapons components, (2) to process source and special nuclear materials, (3) to provide support to the weapons design laboratories, (4) to provide support to other Martin Marietta Energy Systems, Inc., installations, and (5) to provide support to other government agencies. Activities associated with these functions include production of lithium compounds, recovery of enriched uranium from scrap material, and fabrication of uranium and other materials into finished parts and assemblies. Fabrication operations include vacuum casting, are melting, powder compaction, rolling, forming, heat

treating, machining, inspection, and testing. ORNL also operates research facilities at the Y-12 Plant. The ORNL facilities that emit radionuclides include the Biology Division laboratories and the Fusion Energy Division facility.

The source term information from the Y-12 Plant is obtained primarily from the operation of 84 continuous stack sampling systems located on enriched and depleted uranium exhaust stacks operated in 1990. The stacks that were monitored included all process exhausts that were judged to have the potential to emit an environmentally significant quantity of uranium. The potential to emit was judged on the basis of a review of the operations and processes served by the exhaust systems to determine the quantity of uranium handled in the operation or process, the physical form of the uranium, and the nature of the operation or process. These factors determine the potential for uranium to become airborne in a manner that emissions to the environment might result. Approximately 18 of these stacks have the potential to emit radionuclides that could cause a member of the public to receive an effective dose equivalent (EDE) equal to or greater than 0.1 mrem/year.

All emissions of uranium from the Y-12 Plant occur as particulate emissions. Continuous sampling systems were used to monitor emissions from the 84 process exhaust stacks. All the sampling systems on all Y-12 stacks are similar in design to the stack samplers on the Uranium Chip Oxidization Facility, the Uranium Oxide Storage Vault, and the Enriched Uranium Conversion Facility. The Environmental Protection Agency (EPA) Region IV reviewed the design and operation of the sampling systems on these three facilities as a part of the new source approval process. Approval to operate these facilities was received in April 1988. All of the stack sampling systems on the 84 monitored stacks were installed during an upgrade of the emissions monitoring system which was completed in February 1987.

While all major uranium emissions are monitored using the methods described above, it is recognized that some unmonitored emissions occur. These emissions result primarily from room ventilation systems serving uranium process areas, development and laboratory operations, and waste management operations. The source term contains an estimate of these emissions also. The estimate of emissions from room ventilation systems is made by using Health Physics data on airborne radioactivity concentrations in the work areas. The average airborne concentrations are used with estimates of the design ventilation rates for the processing areas to arrive at this estimate. Estimates of this type were developed for eight major process areas. There are a number of minor Radiological Areas for which estimates were not developed for the 1990 assessment. Although it is believed that emissions from these areas are insignificant, they are included in the proposed Radionuclide National Emission Standards for Hazardous Air Pollutants (NESHAP) Compliance Plan that was submitted to EPA on May 1, 1991. Emission estimates from these areas will be developed for the 1991 report.

The Y-12 plant source term also includes estimates for radionuclides emitted from the ORNL Biology and Fusion Energy research facilities. These estimates were based on inventory/use records using the methodology outlined in 40 CFR Part 61, Appendix D.

Source Description: ORNL

ORNL, located toward the west end of Bethel Valley, is a large, multipurpose research laboratory whose basic mission is to expand knowledge, both basic and applied, in areas related to energy.

To accomplish this mission, ORNL conducts research in fields of modern science and technology. ORNL's facilities include nuclear reactors, chemical pilot plants, research laboratories, radioisotope production laboratories, accelerators, fusion test devices, and support facilities. In addition to the main ORNL complex, the ORNL Biology and Fusion Energy divisions and staff from other ORNL divisions are located at the Y-12 Plant, and the Applied Technology Division is located at the K-25 Site.

ORNL radionuclides are emitted from seven monitored stacks and from 112 small emission sources. Small emission sources result from bench-scale laboratory experiments typically conducted in laboratory hoods and are exhausted through small stacks or vents. Emissions from laboratory hoods at ORNL are presented in this report as a grouped source.

Emissions from each stack vary because of the wide variety of research activities performed at ORNL. Radioactive air emissions at ORNL consist mainly of ventilation from isotope production/handling areas, ventilation for reactor facilities, ventilation from analytical facilities, and ventilation from small, bench-scale experiments. Radiological gaseous emissions typically consist of particulates, adsorbable gases (i.e., radioiodine), tritium, and nonabsorbable gases (i.e., noble gases). Continuous stack sampling and laboratory analyses were completed during 1990 to quantify radionuclide emissions from all sources, except the grouped sources consisting of 112 individual point sources. Emissions from the 112 individual point sources were estimated using radionuclide inventory data and methods for estimating radionuclide emissions provided in 40 CFR 61, Appendix D. Grouped source emission estimates did not take advantage of the reduction factors provided in Appendix D for emission control devices. Thus, emission estimates for the grouped source are overestimated.

Source Description: K-25 Site

The Oak Ridge K-25 Site, which is located on Highway 58 near the Clinch River and East Fork Poplar Creek, has several major responsibilities: (1) to provide waste handling and storage capabilities for other DOE facilities; (2) to provide applied technology support for a variety of customers, including DOE and other government agencies; (3) to provide support to DOE decontamination and decommissioning activities; and (4) to provide analytical laboratory support for environmental compliance to DOE facilities. Activities associated with these functions include the Toxic Substance Control Act (TSCA) Incinerator, waste storage and handling, research and development, and fabrication and machining of various components.

The source term information from the K-25 Site is obtained from the operation of one continuous stack sampling system located on the K-1435 TSCA Incinerator and from emissions estimated from grab samples collected in 1990 on two additional sources: the K-1015 Laundry and the K-1419-20 Fluoride Scrubber, Floor Pan, and Cylinder Cleaning Facility. The K-1435 TSCA Incinerator is the only source at the K-25 Site which was judged to have the potential to emit radionuclides that would result in an EDE greater than or equal to 0.1 mrem/year to the most affected resident. The additional two stacks were identified as sources for which grab sampling was an appropriate method for determining emissions. Sources were identified for grab sampling by the review of operations and processes, potential quantity of radionuclides in each process, and the nature of the operation or process.

The continuous sampling system design and operation used to determine emissions from the K-1435 TSCA Incinerator were reviewed by EPA Region IV and approved in October 1987. The grab sampling system design and operation used to estimate emissions from the K-1419-20 Fluoride Scrubber, Floor Pan, and Cylinder Cleaning Facility were also reviewed by EPA Region IV and approved in September 1987. The design and operation of the grab sampling system used to estimate emissions from the K-1015 Laundry was the same as that used on the K-1419-20 Fluoride Scrubber, Floor Pan, and Cylinder Cleaning Facility except that the sample point was upstream of the abatement equipment. The actual emissions were then estimated using the vendor-supplied abatement efficiency.

While all major and some minor uranium emissions are monitored using the methods described above, it is recognized that some unmonitored emissions occur. These emissions result mainly from room and air ventilation systems serving process and waste management areas and development and laboratory operations. An evaluation of potential emissions from all laboratory hoods was conducted. The total quantities of uranium and its isotopes handled in the laboratories were assumed to be released to the atmosphere. In reality, almost no radionuclide emissions would be expected from laboratory activities. Even with these extremely conservative assumptions, the contributions to off-site dose to the maximally exposed individual for the ORR was approximately 0.002 mrem/year. Emission estimates for the other minor sources were not developed for the 1990 assessment. Although it is believed that emissions from these areas are insignificant, those that exist within plant Radiological Areas are included in the proposed Radionuclide NESHAP Compliance Plan that was submitted to EPA on May 1, 1991. Emission estimates for these areas will be developed for the 1991 report.

Section II of this report lists major, minor, and grouped sources for each installation. Major sources are those point sources that have potential emissions that can cause any member of the public to receive a dose greater than or equal to 0.1 mrem/year. Minor sources are point sources that have potential emissions with resulting doses less than 0.1 mrem/year. Grouped sources are two or more minor sources that have been grouped together for reporting purposes. Emissions and resulting doses from grouped sources are less than 0.1 mrem/year.

Section II. Air Emissions Data - Y-12 Plant

Major Point Source ¹	Type of Control ²	Efficiency %	Distance to Receptor ³ (m	
Central Stack ⁴	N/A	N/A	770

75	HEPA Filter Prefilters HEPA Filters	99.97 60 99.97	1000
76	Cyclone Roughing Filters Bag Filter HEPA Filters	50 80 95 99.97	1000

¹The point source number corresponds to the stack radiological monitoring program (SRMP) number.

²Some control devices are final controls that serve all processes exhausted to the stack, while other control devices serve individual processes. Not all stacks have a final control device.

³Distance is expressed as actual distance from the source to the nearest residence, business, school, or farm.

⁴Based on guidance from EPA Region IV (letter from Charles R. Phillips to B. J. Davis, dated January 25, 1985), all Y-12 Plant emissions are assumed to come from a single central stack for modeling purposes. A study has been conducted to show that this assumption results in an overestimate of the dose resulting from Y-12 Plant emissions. Distances used for modeling purposes are outlined in Section III.

⁵High-efficiency particulate air (HEPA) filter.

Section II. Air Emissions Data - Y-12 Plant (continued)

Minor Point or Grouped Source	Type of Control	Efficiency (%)	Distance to Receptor (m)
69 Remaining Monitored Stacks	Cyclones Prefilters Demisters Roughing Filters Dynet Roughing Filters Micrometallic Filters Scrubbers Electrostatic Precipitator Bag House HEPA Filter	50 60 70 80 85 90 90 95 95 95	570 - 1500
Enriched Uranium Room Ventilation (2 Buildings, approx. 20 emission points)	None	N/A	570 - 880
ORNL Biology Division (1 Building, approx. 20 emission points)	HEPA Filter	99.97	900
ORNL Fusion Energy Division (1 Building, 2 emission points)	HEPA Filter	99.97	1280
Depleted Uranium Room Ventilation (6 Buildings, approx. 40 emission points)	None	N/A	570 - 1320

¹The remaining 69 monitored stacks contribute as a group approximately 4% of the plant dose. The emissions from these monitored stacks are controlled by a variety of emissions control equipment ranging from no control device to HEPA filtration. The different types of control devices that may be found on these stacks have been listed with their estimated control efficiency.

Section II. Air Emissions Data - ORNL

Major Point Source	Type of Control ¹	Efficiency (%)	Distance to Receptor ² (m)
X-2026	HEPA Filters Charcoal Filters	99.97 90 ³	3930
X-3020	HEPA Filters	99.97	4030

New and Modified Sources

No new sources or modifications of existing sources were completed during 1990 at the ORR.

Section III. Dose Assessments

Description of Dose Model

The radiation dose calculations were performed using the CAP-88 package of computer codes. This package contains EPA's most recent version of the AIRDOS-EPA computer code, which implements a steady-state, Gaussian plume, atmospheric dispersion model to calculate environmental concentrations of released radionuclides. Regulatory Guide 1.109 foodchain models are used to calculate human exposures, both internal and external, due to radionuclides deposited in the environment. The human exposure values are then used by the EPA's latest version of the DARTAB computer code to calculate radiation doses to man from radionuclides released during the year. The dose calculations use dose conversion factors in the latest version of the RADRISK data file, which is provided by the EPA with the CAP-88 package.

Summary of Input Parameters

Except for those given below, all important input parameter values used are the default values provided with the CAP-88 computer codes and data bases.

Meteorological data:

ORNL: 1990 STAR data from the 100-m station on MT2.

K-25: 1990 STAR data from the 60-m station on the K-25 Site tower.

Y-12: 1990 STAR data from the 30-m station on the East tower.

Rainfall rate: 152 cm/year Average air temperature: 15°C Average mixing layer height: 1000 m

The solubility classes used for radionuclides released by ORNL were those that would give the highest dose.

Compliance Assessment

Effective Dose Equivalent:	2 mrem*
----------------------------	---------

^{*}Calculated effective dose equivalent for ORR was 1.7, which was rounded to 2 mrem/year. The estimated contribution to off-site dose due to small unmonitored sources at the Y-12 Plant, ORNL, and K-25 Site were approximately 0.3, 0.0005, and 0.002 mrem/year, respectively. The most exposed member of the public for the ORR is located approximately 1080 meters north of the Y-12 Plant.

Certification

I certify under penalty of law that I have personally examined and am familiar with the information submitted herein and, based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the submitted information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment. (See 19 U.S.C. 1001).

Section IV. Supplemental Information*

Dose Equivalents to Specific Organs (mrem)

Organ/tissue	<u>Y-12</u>	ORNL	<u>K-25</u>	ORR
Effective	2	0.2	0.006	2
Whole Body	0.002	0.2	0.000007	0.1
Lung	10	0.2	0.05	10
Endosteum	0.8	0.1	0.006	1
Red Marrow	0.05	0.2	0.0006	0.2

Collective Effective Dose Equivalent (person-rem/year) - 50 mile radius

Installation	Person-rem
Y-12	20
ORNL	4
K-25	0.2
ORR	30

Status of Compliance with NESHAP Monitoring Requirements of Subpart H

The status of compliance with the new NESHAP monitoring requirements is thoroughly described in the revised NESHAP Compliance Plan, which was submitted to EPA-IV on May 1, 1991.

Unplanned Releases

See Tables I and II for a list of the unplanned releases at the Y-12 Plant and K-25 Site, respectively. ORNL did not have any unplanned releases during 1990.

Diffuse and Fugitive Emissions

It is anticipated that emissions due to diffuse and fugitive emissions do not contribute significantly to off-site dose. However, the ORR does not currently have any available methods to selectively estimate emissions of diffuse and fugitive emissions. Ambient air monitoring has historically demonstrated that measured radionuclide concentrations and resulting dose are less than predicted by computer dispersion modeling and dose assessments for emissions associated with point sources. These data reaffirm the assumption that diffuse and fugitive emissions do not contribute significantly to off-site dose.

^{*}For DOE information only. Not for submittal to EPA.

^{*}Indicates method of estimating source term. "Measured" indicates that the source term was estimated on the basis of monitoring data. "Potential" indicates that the source term was estimated using Appendix D of 40 CFR 61; however, no consideration to controls was assumed.

TABLE I UNPLANNED RELEASES FOR THE Y-12 PLANT^{1,2}

	UN	JNPLANNED RELEASES FOR THE Y-12 PLANT ^{1,2}		
Stack	<u>Date</u>	Description	Corrective Action	
36	02/24/90	Improper operation; Unfiltered wet exhaust	Cleaned system and sampler; reviewed procedures	
42	02/25/90	Equipment failure	Repaired equipment, cleaned system	
27	06/20/90	Unknown	Checked/cleaned system	
27	08/10/90	Unknown	Checked/cleaned system	
17	09/14/90	Process fluctuation	Checked system	
36	09/ 08 thru 09/ 09/90	Process fluctuations; Unfiltered wet exhaust	Cleaned system and sampler	
47	11/09/90	Process fluctuation	Checked system	
36	11/29/90	Invalid sample, internal procedural deviation	Reviewed and updated procedures	
27	11/30/90	Process fluctuation	Checked system and sampler	
15	11/27/90	Unknown	Checked systems	
11	12/19/90	Water in exhaust system: Wet sample		
64	12/19/90	Process fluctuation	Checked system	
27	12/22/90	Process fluctuation	Checked system	
11	12/28/90 thru 01/2/91	Water in exhaust system;	Pumped water out, cleaned sample	

The specific quantities released are minimal and classified. The data are on file at the Y-12 Plant. The dose from these individual small quantities is known to be insignificant based on annual emission quantities and resultant doses. The quantities released are included in the annual emission totals.

²DOE release reporting criteria under DOE Order 5000.3A was modified in September 1990; therefore, more frequent unplanned releases are noted after September 1990.

TABLE II UNPLANNED RELEASES FOR THE K-25 SITE¹

Building	<u>Date</u>	December 1	
	34.0	Description	Corrective Action
K-31	06/26/90	UF ₆ out-gassing during compressor removal.	Compressor and pipe openings covered and air samples taken.
K-25	11/20/90	UF ₆ gas release from partially welded pipe.	Opening sealed and air samples taken.

These releases were so small that modeling was not conducted; therefore, an EDE for these releases was not calculated.

Map showing the Department of Energy's Oak Ridge Reservation and the location of the three major

installations.
